Introduction

- Conventionally graphs are represented as adjacency matrices, or adjacency lists. Algorithms are designed with such representations in mind usually.
- It is better to look at the structure of graphs and find some representations that are suitable for designing algorithms- say for a class of problems.
- Intersection graphs: The vertices correspond to the subsets of a set U. The vertices are made adjacent if and only if the corresponding subsets intersect.
- We propose to use some nice geometric objects as the subsets- like spheres, cubes, boxes etc. Here U will be the set of points in a low dimensional space.

Introduction

- Motivation

- There are many situations where an intersection graph of geometric objects arises naturally....
- Some times otherwise NP-hard algorithmic problems become polytime solvable if we have geometric representation of the graph in a space of low dimension.

Boxicity and Cubicity

- Cubicity: Minimum dimension k such that G can be represented as the intersection graph of k-dimensional cubes.
- Boxicity: Minimum dimension k such that G can be represented as the intersection graph of k-dimensional axis parallel boxes.
- These concepts were introduced by F. S. Roberts, in 1969, motivated by some problems in ecology.
- By the later part of eighties, the research in this area had diminished.

Basic Theory

An Equivalent Combinatorial Problem

- The boxicity(G) is the same as the minimum number k such that there exist interval graphs l₁, l₂,..., l_k such that G = l₁ ∩ l₂ ∩ ··· ∩ l_k.
- Similarly, cubicity(G) is the minimum number k such that there exists unit interval graphs l₁,..., l_k such that G = l₁ ∩ · · · ∩ l_k.

How to show a graph of high boxicity

- Let G be the complement of a perfect matching on n vertices. (Assume n is even).
- Suppose it is the intersection n/2 1 interval graphs.
- Then out of the n/2 missing edges of G, at least 2 should be missing in the same interval graph- by pigeon hole principle.

llSc

- Then it cannot be an interval graph, since there will be an induced 4 cycle !
- So, the boxicity of this graph is at least n/2.

First Approach

Non-edge by Non-edge

Intersection Graphs

Basic Theory

A Simple Upper Bound

- Take a vertex u.
- Map u to the interval [0, 1].
- Map each vertex in N(u) to [1,2].
- Map each vertex in $V (\{u\} \cup N(u))$ to [2,3].
- Do the same thing for each vertex u. We get n interval graphs.

llSc

(日) (日) (日) (日) (日) (日) (日) (日)

So, boxicity of $G \leq n$.

Intersection Graphs
Basic Theory

How to Improve the above strategy

- Can we deal with 2 vertices at a time ?
- What kind of pairs can be selected ? Roberts suggests to pick a pair of non-adjacent vertices.
- Let *u* and *v* be non-adjacent.
- Let u be given [0,1] and v be given [4,5].
- Remaining vertices belong to one of $S_0 = N(u) \cap N(v)$, $S_1 = N(u) - S_0$, $S_2 = N(v) - S_0$. $S_3 = V - (N(u) \cup N(v))$.

llSc

- To vertices of S_0 give [1, 4]
- To vertices of S_1 give [1, 2.5]
- To vertices of S_2 give [2.5, 4]
- To vertices of S₃ give [2,3]
- Repeat the procedure. When do we get stuck ?
- This strategy gives an upper bound of $\lceil n/2 \rceil$

Intersection Graphs

More Results

Boxicity and Maximum Degree

Boxicity of any graph is at most $2\Delta^2$, where Δ is the maximum degree of the graph.

(The only previous known upper bound was n/2 where n is the number of vertices)

llSc

More Results

Cubicity of any graph is $O(\Delta \log n)$, where Δ is the maximum degree and *n* is the number of vertices. For the first time, we applied probabilistic tools in the study of boxicity and cubicity.

-More Results

We related cubicity and boxicity with width parameters such as bandwidth and treewidth.

1 boxicity(
$$G$$
) \leq treewidth(G) + 2.

Treewidth is a very well studied parameter. This allowed us to get many results regarding boxicity.

llSc

(ロ) (型) (E) (E) (E) (E) (O)(O)

-More Results

The following consequence of the treewidth upper bound is interesting.

For a chordal graph, boxicity is at most $\chi(G) + 1$.

-More Results

- cubicity(G) \leq bandwidth(G) + 1.
- cubicity(G) = O(b log n), where b is the bandwidth and n is the number of vertices.

llSc

(ロ) (型) (E) (E) (E) (E) (O)(O)

More Results

Another upper bound: boxicity $(G) \leq \lfloor \frac{t}{2} \rfloor + 1$, where *t* is the cardinality of the minimum vertex cover in *G*.

More Results

Some other results we obtained

Cubicity of *d*-dimensional hypercubes is $\Theta(d/\log d)$.

-More Results

The Claw Number: Let ψ be the largest integer such that there exists an induced star on $\psi + 1$ vertices in G. The ψ is called the claw number of G.

Cubicity of an interval graph is O(log ψ).
 Note that ψ ≤ Δ.

More Results

Let G be an AT-free graph. Then:

- boxicity(G) $\leq \chi(G)$.
- cubicity(G) \leq box (G).($\lceil \log \psi(G) \rceil + 2$)
- If girth of G is at least 5, then $boxicity(G) \le 2$.

llSc

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ● ● ● ● ● ●

More Results

Lower bounds for boxicity: We came up with two general methods to derive lower bounds for boxicity. Applying these methods we could derive many results, some of which are listed below.

- The boxicity of almost all graphs is $\Omega(d_{av})$, where d_{av} is the average degree of the graph.
- If the minimum degree is δ , then boxicity is at least $\frac{n}{2(n-\delta-1)}$
